

## Solutions to Test 2.

1 a) There is one field of size  $8^2 = 2^6$  and one field of size  $9^2 = 3^4$ . There are no fields of size 100.

b) In  $\mathbb{Z}_2[x]$ ,  $x^2 + 1 = (x+1)^2$  so it is reducible.

In  $\mathbb{Z}_3[x]$ ,  $x^2 + 1$  has no roots so it is irreducible.

2. a)  $\phi(77) = 6 \cdot 10 = 60$

$$60 = 8 \cdot 7 + 4 \quad \text{so by back sub.} \quad 1 = 2 \cdot 60 - 17 \cdot 7$$

$$7 = 4 + 3$$

$$4 = 3 + 1$$

so the deciphering exponent is  $-17 \equiv 43 \pmod{60}$ .

b) To encode  $m = 7$ , we compute  $7^7 \equiv \quad \pmod{77}$ .

3. The most commonly used primality test is the Miller-Rabin algorithm. It is a probabilistic test which will tell you definitively if a number is composite and with reasonable probability correctly identify if the number is prime. The algorithm works like this:

Pick a number  $a$  with  $\gcd(a, n) = 1$ . Write  $n-1 = 2^k m$  for an odd number  $m$ . Compute a sequence  $b_0, b_1, \dots, b_k$  s.t.  $b_0 \equiv a^m \pmod{n}$  and  $b_{i+1} \equiv b_i^2 \pmod{n}$  for  $i < k$ .

If  $b_0 \equiv \pm 1 \pmod n$  or if  $b_i \equiv -1 \pmod n$  for any  $i$ , the algorithm declares  $n$  is prime. Otherwise it says  $n$  is composite. It will always be correct if it says composite and will be correct at least 75% of the time if it says prime.

To increase the chances of being correct if prime is returned, typically one runs the algorithm for several randomly chosen  $a$ .

4. From the question,

$$A = \left( 880525 \times 2057202 \times 648581 \right)^2 \equiv 2 \cdot 6 \cdot 3 = 6^2 \pmod{2288233}$$

We also have  $A \equiv 720341 \pmod{2288233}$

So  $A^2 \equiv 6^2 \pmod{2288233}$  and  $A \not\equiv \pm 6$  so

$\gcd(2288233, 720341 - 6)$  divides 2288233

With a calculator, compute the gcd:

$$2288233 - 3 \cdot 720335 = 127228$$

$$720335 - 5 \cdot 127228 = 84195$$

$$127228 - 84195 = 43033$$

$$84195 - 43033 = 1871$$

and  $1871 \mid 43033$

$$\text{So } 2288233 = 1871 \times 1223.$$

You could have also similarly calculated  $\gcd(2288233, 720347)$  and got 1223.

5. Suppose  $F$  is finite and consider the sequence  $1, 1+1, 1+1+1, \dots$  where we write  $k \cdot 1$  for  $\underbrace{1+1+\dots+1}_{k \text{ times}}$ .

Since  $F$  is finite, for some  $k < l$ ,  $k \cdot 1 = l \cdot 1$ .  
But then  $(l-k) \cdot 1 = 0$ . So there is some  $m$  s.t.  $m \cdot 1 = 0$ .  
Choose the least such  $m$  and suppose  $m = k \cdot l$  where  $1 < k, l < m$  i.e. suppose  $m$  is composite.

$$\begin{aligned} \text{Compute } (k \cdot 1) \cdot (l \cdot 1) &= \underbrace{(1+\dots+1)}_k \underbrace{(1+\dots+1)}_l \\ &= \underbrace{(1+\dots+1)}_l + \underbrace{(1+\dots+1)}_l \dots \underbrace{(1+\dots+1)}_l \\ &\quad \underbrace{\hspace{10em}}_{k \text{ times}} \\ &= m \cdot 1 = 0 \end{aligned}$$

So  $k \cdot 1 = 0$  or  $l \cdot 1 = 0$  since  $F$  is a field. This contradicts the minimality of  $m$ . So  $m$  is prime.
